## <sup>8</sup> Summary

<sup>9</sup> The control of quantum systems lies at the heart of quantum computation and is studied via <sup>10</sup> the dynamical Lie algebra (DLA), i.e. the Lie algebra that is generated by terms in the system's <sup>11</sup> Hamiltonian. Tensor products of Pauli matrices (Pauli strings) form a basis of Hermitian <sup>12</sup> operators and as such appear as generators in trotterized Hamiltonian simulation. Moreover, <sup>13</sup> they naturally arise as effective control Hamiltonians in trapped-ion systems and also occur in <sup>14</sup> measurement-based quantum computation. While a conceptually complete classification of <sup>15</sup> systems that are generated by Pauli strings is known, this classification was not packaged as an <sup>16</sup> explicit, scalable procedure, and therefore remained difficult to deploy in concrete design tasks. <sup>17</sup> Within the Python package `paulie` we present an efficient algorithm for this classification that <sup>18</sup> directly allows to study the controllability of Pauli string generated systems. We showcase the <sup>19</sup> utility of our framework by numerically providing the optimal universal generator sets.

## <sup>20</sup> Statement of need

<sup>21</sup> The dynamical Lie algebra (DLA) is generated via nested commutation of the interaction <sup>22</sup> terms in the system's Hamiltonian. It constitutes the tangent space of the associated Lie <sup>23</sup> group which captures the possible trajectories of the evolving quantum system. Therefore, <sup>24</sup> the DLA is a pivotal tool to study the symmetries and dynamics of quantum systems and <sup>25</sup> occurs in various fields within quantum information theory such as quantum control ([Zeier & Schulte-Herbrüggen, 2011](#)), simulation ([Goh et al., 2025](#)) and quantum machine learning <sup>26</sup> [Ragone et al. \(2024\)](#).

<sup>27</sup> Pauli strings form a basis for Hermitian operators and as such appear as generators in <sup>28</sup> trotterized Hamiltonian simulation ([Trotter, 1959](#)). They also arise as native gate sets in <sup>29</sup> trapped ion systems ([Nam et al., 2020](#)) and occur in measurement-based quantum computation <sup>30</sup> ([Raussendorf et al., 2003](#)).

<sup>31</sup> A recent line of work ([Kökçü et al., 2024](#); [Wiersema et al., 2024](#)) culminated in a classification <sup>32</sup> of DLAs generated by arbitrary sets of Pauli strings ([Aguilar et al., 2024](#)). While conceptually <sup>33</sup> complete, this classification was not packaged as an explicit, scalable procedure, and therefore <sup>34</sup> remained difficult to deploy in concrete design and compilation tasks. This work provides a <sup>35</sup> bridge as we provide an efficient algorithm that takes any set of Pauli strings and outputs its <sup>36</sup> DLA. This allows the direct study of controllability of quantum systems generated by Pauli <sup>37</sup> strings. In addition equivalences of generating sets can be easily checked and transitions <sup>38</sup> between algebras by changing the generator set studied. We demonstrate the utility of the <sup>39</sup> framework by constructing universal generator sets with optimal generation rate.

## 41 Preliminaries

42 A state of an isolated physical system is represented at a fixed time  $t$  by a vector  $|\psi\rangle$  in a  
 43 Hilbert space  $\mathcal{H}$ , that is, a complex vector space endowed with an inner product. The time  
 44 evolution of the state is determined by the Schrödinger equation  $i\frac{d}{dt}|\psi\rangle = H|\psi\rangle$ , where we  
 45 set  $\hbar = 1$ .  $H$  is the Hamiltonian that describes the observable corresponding to the total  
 46 energy of the system. An observable is a Hermitian linear map acting on  $\mathcal{H}$ . The solution  
 47 to this differential equation with initial state  $|\psi_0\rangle$  and time-independent Hamiltonian  $H$  is  
 48  $|\psi(t)\rangle = e^{-iHt}|\psi_0\rangle$ . We specify a set of operators  $\mathcal{G} = \{h_j\}_{j \in J}$  that describe the ways in  
 49 which we can control the quantum system and that corresponds to the individual interaction  
 50 terms of the Hamiltonian. The reachable states are then of the form

$$|\psi(t)\rangle = e^{-ih_{l_m}t_{l_m}} \dots e^{-ih_{l_1}t_{l_1}} |\psi_0\rangle \quad (1)$$

51 for some index set  $\{l_i\}_{i=1}^m \subset J$ . The associated matrix Lie algebra  $\mathfrak{g}$ , that is, a real subspace of  
 52 complex matrices that is closed under the matrix commutator  $i[h, g] = i(hg - gh)$ , is dubbed  
 53 dynamical Lie algebra (DLA). Hence, the elements of  $\mathcal{G}$  span all elements in  $\mathfrak{g}$  through nested  
 54 commutators,  $\mathfrak{g} = \text{span}_{\mathbb{R}}\langle\mathcal{G}\rangle_{Lie}$ . In case the generator set  $\mathcal{G}$  consists of tensor products of  
 55 Pauli matrices (Paulistrings),  $\mathfrak{g}$  is termed Pauli Lie algebra.

56 The classical compact simple Lie algebras are

$$\mathfrak{su}(d) = \{x \in \mathbb{C}^{d \times d} | x = -x^\dagger, \text{tr } x = 0\} \quad (2)$$

$$\mathfrak{so}(d) = \{x \in \mathbb{R}^{d \times d} | x = -x^T\} \quad (3)$$

$$\mathfrak{sp}(2d) = \{x \in \mathfrak{su}(2d) | x = -\Omega x^T \Omega^T\} \quad (4)$$

57 where the symplectic form is denoted as

$$\Omega = \begin{pmatrix} 0 & \mathbb{I}_d \\ -\mathbb{I}_d & 0 \end{pmatrix}. \quad (5)$$

58 Considering a system out of  $n$  qubits, the Hilbert space is  $\mathcal{H} = \mathbb{C}^{2^n}$ . A generator set that  
 59 spans all of  $\mathfrak{su}(2^n)$  is called universal, and the system is fully controllable. To characterise  
 60 spin chains, we employ the following graph

61 **Definition 1** *The anticommutation graph has  $\mathcal{G}$  as a node set and the edges are between the*  
 62 *generators that anticommute  $E = \{(p, q) | [p, q] \neq 0\}$ .*

## 63 Classification algorithm

### 64 Optimal universal generator set

65 With the feature `get_optimal_su_2_n_generators` we find among all universal generator sets  
 66 those that have optimal generation rate, i.e. the sets that generate  $\mathfrak{su}(2^n)$  the fastest. In  
 67 (Smith et al., 2025) it is derived that these are exactly generating sets with a fraction of  
 68 anticommuting pairs of generators out of the total number of pairs to be approximately 0.706.  
 69 Analytically this fraction maximizes a particular q-Pochhammer symbol. We can reframe the  
 70 problem in terms of the anticommutation graph. Optimal universal generating sets have an  
 71 anticommutation graph with approximately  $\lfloor 0.706 \cdot \binom{n}{2} \rfloor$  edges. To search for such graphs, we  
 72 start with the canonical graph of  $\mathfrak{su}(2^n)$ . We can obtain the canonical graph by the algorithm  
 73 described in the previous section. The canonical graph is the anticommutation graph with  
 74 minimal connectivity, hence we are guaranteed to be below the target anticommutation fraction.  
 75 We iterate over the edge set of the canonical graph and perform a contraction such that the  
 76 anticommutation fraction increases and become closer to the target value until we reach the

77 target value. In the following example of usage we find the optimal universal Pauli string  
78 generator set in dimension four.

```
79 .. code-block:: python  
80     from paulie.application.get_optimal_su2_n import get_optimal_su_2_n_generators  
81     from paulie.common.two_local_generators import G_LIE  
82     from paulie.common.pauli_string_factory import get_pauli_string as p  
83  
84     n = 4 # dimension of the system  
85     initial_generators = p(G_LIE["a12"], n=n) # some universal generator set  
86     optimal_generators = get_optimal_su_2_n_generators(initial_generators)  
87     print(f" {optimal_generators} fraction={optimal_generators.get_anticommutation_fraction()  
88 which outputs:  
89 .. code-block:: bash  
90     XZYX,ZZXZ,IYYY,XZYY,IXZX,YYXY,YYYY,ZZIX,XXZY fraction=0.6944444444444444
```

## 91 **Citations**

92 Citations to entries in paper.bib should be in [rMarkdown](#) format.

93 If you want to cite a software repository URL (e.g. something on GitHub without a preferred  
94 citation) then you can do it with the example BibTeX entry below for (?).

95 For a quick reference, the following citation commands can be used: - @author:2001 ->  
96 "Author et al. (2001)" - [@author:2001] -> "(Author et al., 2001)" - [@author1:2001;  
97 @author2:2001] -> "(Author1 et al., 2001; Author2 et al., 2002)"

## 98 **Figures**

99 Figures can be included like this: Caption for example figure. and referenced from text using  
100 [section](#).

101 Figure sizes can be customized by adding an optional second parameter: Caption for example  
102 figure.
